

Offsetting with Confidence:

How CNaught Constructs a High-Quality Portfolio of Carbon Offsets

Executive Summary

While there is broad agreement that carbon offsets are a powerful tool in the fight to avoid the worst effects of climate change, it is far too hard to be a buyer of carbon offsets today. Offset projects vary wildly on basic features like price, availability, and even whether they have climate impact at all. This makes it difficult and time-consuming for a non-expert buyer to sort through all of the noise and have confidence in their choices.

CNaught gives offset buyers confidence by (1) building an offset portfolio that supports multiple project types and (2) conducting deep due diligence to ensure that every project is driving real impact. In doing so, CNaught makes a high-quality portfolio of carbon offsets available to everyone.

Carbon Offsets Are a Necessary Tool for Addressing Climate Change

The evidence is clear: we are facing a climate emergency driven by our simultaneous emission of greenhouse gasses and destruction of nature-based carbon sinks. To avoid the worst impacts of climate change, the Intergovernmental Panel on Climate Change (“IPCC”) has set a goal to keep global temperature increases to no-more-than 1.5°C above pre-industrial levels.¹ This requires a reduction in global emissions of 45% from 2010 levels by 2030 and net-zero emissions by 2050.² It is estimated that any pathway to keeping temperature increases below 1.5°C will require between 100 and 1,000 gigatons of carbon removal over the course of the 21st century.³

“Companies and organizations will need to use every tool at their disposal to achieve emission reduction goals. ‘Carbon offsets’ are one such tool that – if used responsibly – can accelerate action to avert dangerous climate change.”⁴

– The Stockholm Environmental Institute

⁴ Securing Climate Benefit: A Guide to Using Carbon Offsets, at 5 (Nov. 13, 2019) (available at: http://www.offsetguide.org/wp-content/uploads/2020/03/Carbon-Offset-Guide_3122020.pdf).

Carbon offsets are an important part of the pathway to Net Zero. While there is broad agreement that we should reduce our emissions as much as possible, there is also widespread agreement that credible offsets are a critical piece of the climate puzzle.⁵ Offsets are particularly necessary for hard-to-decarbonize industries because zero emission options for things like aviation fuel and industrial processes may not be available by 2050.⁶ We need effective carbon offsets to help us avoid the worst effects of climate change.

The concept of carbon offsets is easy to understand. A carbon offset is a reduction or removal of emissions of carbon dioxide or other greenhouse gases that compensates for an equivalent emission somewhere else. Carbon offsets can sometimes also be called carbon credits, though we use offsets to refer to purchases in a voluntary market and credits for purchases made in a regulated market.

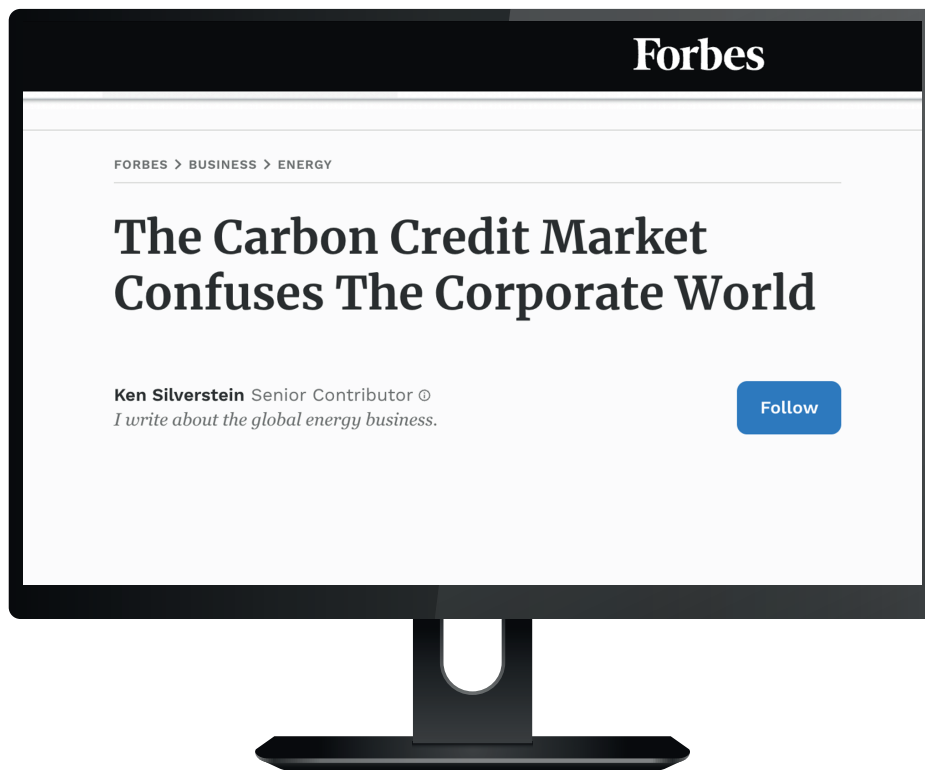

Offsets are typically measured in metric tons of carbon dioxide-equivalent (“CO₂e”) so that they can ideally be treated as interchangeable, no matter where or how a reduction or removal occurs or the kind of greenhouse gas that is reduced or removed. An offset buyer therefore pays a price per ton of carbon that directly offsets their emissions elsewhere. In this simple concept, offsets should be a commodity, different carbon offsets should be interchangeable, a ton of carbon should be a ton of carbon, and it would be easy to be a buyer.

Unfortunately, that is not how carbon offsets actually work.

⁵ See, e.g., The Climate Pledge: <https://www.theclimatepledge.com/>.

⁶ See The Oxford Principles for Net Zero Aligned Carbon Offsetting at 3 (September 2020) (available at: <https://www.smithschool.ox.ac.uk/sites/default/files/2022-01/Oxford-Offsetting-Principles-2020.pdf>).

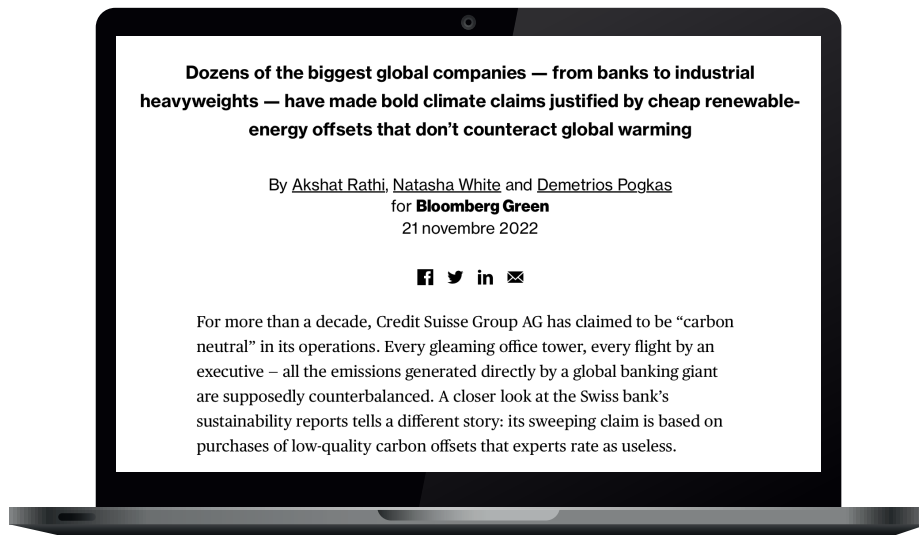

Offset Quality Can Vary Widely Across a Number of Different Axes

In reality, carbon offsets vary widely in quality, and it is difficult for non-expert buyers to identify high-impact offsets consistently. In the offset world, quality means that a carbon offset representing a metric ton of CO₂e *actually* is responsible for a reduction or removal of a metric ton of CO₂e. There are several key attributes of offset quality:

Additionality: To be additional, an offset must “represent an emission reduction or carbon removal relative to a counterfactual baseline that would not have taken place” if not for the ability to sell offsets.⁷ If the ton would have been removed or avoided anyhow—for instance, because regulations required the project activity or because the activity was profitable absent the offset—the offset is not doing any work and does not actually subsidize the removal or avoidance activity.

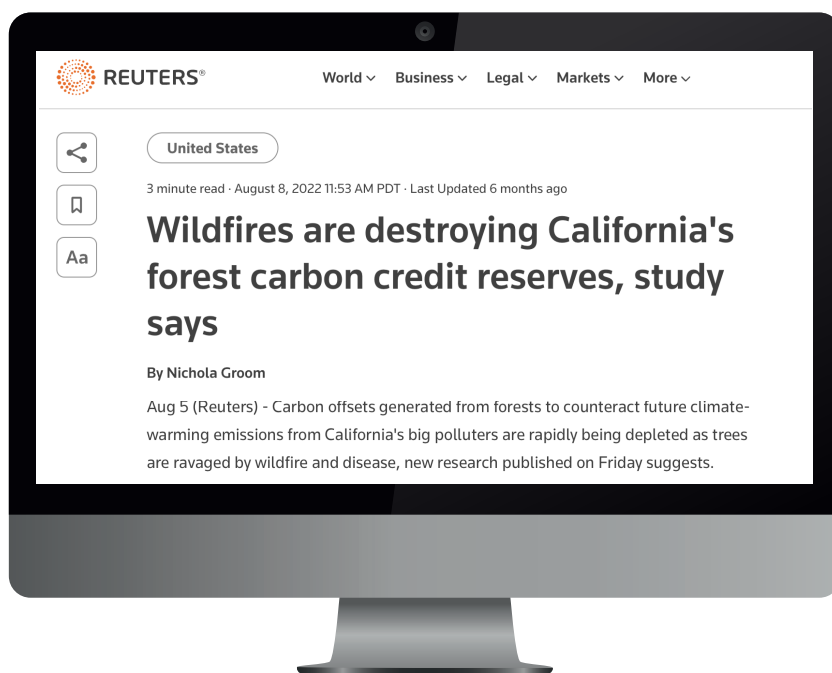

Companies have faced criticism for supporting renewable energy offsets that are not additional: in many cases, the projects are economically viable without carbon offsets.

⁷ The Oxford Principles at 5; see also Securing Climate Benefit at 19.

Durability: A metric ton of CO₂e, by its terms, is silent about how long an emission will be avoided or how long a removal would be stored. Yet durability—sometimes also called permanence—is a critical input to the quality of an offset. 25% of every ton of emitted CO₂ remains in the atmosphere for hundreds to thousands of years,⁸ so carbon must be avoided or stored for long periods of time to meaningfully offset the emission. Durability can be an issue both during the life of a project (e.g., what happens if there is a forest fire?) and after (e.g., what happens to the forest after the project ends?).

Fires and infestation can undermine the durability of carbon storage in forest offsets.

Avoiding Over-crediting Risk: While projects may actually be removing or avoiding CO₂, there are several different ways that a project developer can overstate the amount of CO₂ their project is avoiding or removing. If the amount is overstated, the impact of each offset is overstated proportionally.

- **Overestimation of the Baseline:** A carbon offset represents the value of what happened because of the offset minus what would have happened if there were no offset.⁹ If the project overestimates what would have happened but for the offsets, each offset issued by the project will not represent an actual metric ton of CO₂e.
- **Underestimating Actual Emissions:** If projects have residual emissions after the offsetting activity, mismeasuring those residual emissions can similarly overstate the impact of the offsets.¹⁰
- **Leakage:** Projects must accurately model their indirect effects, or else they will be simply shifting emissions from the project location to another location.¹¹ To take the simplest example, an offset is not effective if it preserves one forest but simply shifts logging activity to the forest next door.

Forestry offsets can dramatically overstate their impact by relying on overly pessimistic baselines.

⁹ See generally *id.* at 23.

¹⁰ See generally *id.*

¹¹ See generally *id.*

Avoiding Double-Counting: Each ton of carbon removed or avoided can only generate one offset for one buyer. What's more the avoided or removed emission cannot be separately claimed by the project developer if they are also selling it as an offset.¹² An offset buyer must be sure they are getting the exclusive right to the ton of carbon.

Choosing the Wrong Offsets Has Real Downsides

- ✓ If an offset doesn't actually lead to removed or avoided carbon, the buyer is not actually getting what they paid for and the climate is worse off than it should be.
- ✓ Project developers are not incentivized to develop projects that deliver real impact.
- ✓ The public could lose trust in carbon offsets. Offsets are one of the best tools we have to make an immediate dent in climate change, but they have to deliver impact for the public to believe in their promise.
- ✓ A buyer typically purchases offsets voluntarily because they want to do their part to address the climate crisis. If the offsets don't deliver, what should be a brand benefit can become a brand detriment.
- ✓ The offset market as a whole is smaller than it should be because some buyers may choose to stay on the sidelines in the face of uncertainty.

Most Buyers Should Be Purchasing a Portfolio of Offsets to Drive Impact and Mitigate Risk

Building a portfolio of carbon offsets across project types and geographies maximizes climate impact and mitigates the risk of offset selection. In the same way that non-performance of a single stock in an index-fund does not overly reduce the returns of the fund as a whole, diversification across multiple projects reduces the quality impact of a problem with any single project and ensures that a buyer still drives climate impact. This approach reflects research recommending the best ways to reduce risk when using carbon offsets,¹³ it is followed by the most cutting-edge companies using offsets, like Stripe and Shopify, and it is recommended by the World Economic Forum.¹⁴

¹³ See, e.g., SGFC, Forestry Backed Assets Design (December 2022) (available at: <https://imperialcollegelondon.app.box.com/s/ejajo17eynozt9c5hndd1y3yfpvctqvs>).

¹⁴ See World Economic Forum, The Voluntary Carbon Market: Climate Finance at an Inflection Point (January 2023) (available at: https://www3.weforum.org/docs/WEF_The_Voluntary_Carbon_Market_2023.pdf).

In September 2020, the University of Oxford published the Oxford Principles for Net Zero Aligned Offsetting. The guidance recommends that offset buyers (i) purchase a portfolio that covers various technologies and (ii) reweight that portfolio over time as new technologies come online and emissions patterns change. The Oxford Principles set out a blueprint for how to buy a balanced portfolio that drives impact at scale and supports the global transition to Net Zero by 2050.

The Oxford Principles set out five categories of offsets that should make up a portfolio:

- **Type 1:** Avoided Emissions or Emissions Reductions without Storage: This category can include projects like renewable energy, cleaner cookstoves, or capturing methane emissions.
- **Type 2:** Emissions Reductions with Short-Lived Storage: This category can include projects like avoided deforestation, with storage typically coming in plants, trees, or soil.
- **Type 3:** Emissions Reductions with Long-Lived Storage: This category typically is industrial, point source carbon capture (e.g., at a smokestack), with the carbon then stored for the long-term, for instance in underground caves or wells. There is currently a limited availability of this category of offsets.
- **Type 4:** Carbon Removal with Short-Lived Storage; This category involves removing existing carbon from the air and storing it in new plants, trees, or soil through steps like reforestation or ecosystem restoration.
- **Type 5:** Carbon Removal with Long-Term Storage: These tend to be cutting-edge technological solutions that, currently, have a lot of promise but have limited availability and are not yet ready for scale. Good examples include direct air capture technology and storage of carbon through enhanced rock weathering.

The Oxford Principles recognize that, over time and in order to reach Net Zero, buyers should be moving from avoided emissions to carbon removal and from short-term to long-term carbon storage. Put differently, by 2050 a portfolio should be heavily weighted toward Type 5. However, the Principles also recognize that starting with such a portfolio “is not necessary, nor is it currently feasible.”¹⁵

CNaught makes it easy to access a portfolio of high-quality carbon offsets

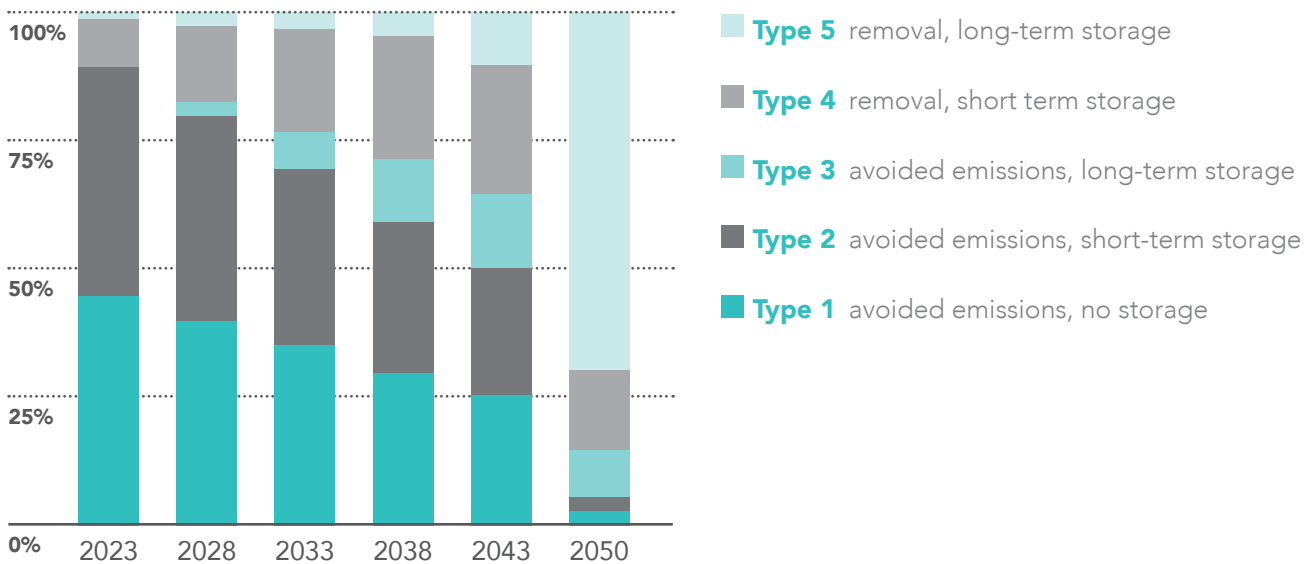

CNaught does the hard work of selecting offset projects and building a high-quality offset portfolio for our customers. The offset market is hard to navigate, so we believe it is insufficient to provide information to buyers so that they can do their own research and build their own expertise. For CNaught customers, all it takes is a handful of clicks to procure a high-quality offset portfolio. Here is how we do it:

CNaught's Portfolio of Offsets Drives Impact by Finding Quality and Mitigating Risk

CNaught follows the best science to construct an offset portfolio balanced for impact, to mitigate risk within that portfolio, and to select high-quality projects for that portfolio.

The Right Portfolio. To drive impact now, our portfolio is currently weighted toward high-quality emissions reductions that are already available at scale. Consistent with the Oxford Principles, the weight of our portfolio will shift toward removals over the coming decades. Even now, however, we dedicate some of our portfolio toward removals with long-term storage because creating demand for those kinds of projects will incentivize the technological development we need.

Illustrative Example of How the CNaught Portfolio May Evolve Over Time

Mitigating Risk. Within our portfolio, we diversify across technologies and geographies to mitigate risk. Research indicates that the performance of different offset projects are not correlated, so having a portfolio that includes different projects using different technologies in different locations is a core way to mitigate the risk of a single non-performing project.

Project-By-Project Diligence. At the project level, we do in-depth due diligence to find the projects most likely to deliver real impact. In the fractured world of carbon offsets, there are resources like the Carbon Offset Guide¹⁶ and project ratings agencies like Calyx Global and Renoster that can help buyers do the arduous work of sorting through different projects. For every project we consider, we rely on available inputs from those resources, and then we do our own review across the criteria that constitute project quality:

¹⁶ See Securing Climate Benefit.

- **Additionality:** We ensure that projects would not have happened without the sale of carbon offsets. We look at things like the economic feasibility of the project without offsets or whether the policy environment already requires the steps taken by the project to determine whether the project is additional.
- **Durability:** Our approach to durability varies somewhat by project type. For certain types of projects, like methane destruction, durability may not be an issue. However, for nature-based solutions we look closely at things like the lifetime of the project, whether the project is adequately prepared for events like fires or infestations during the project lifetime (and whether such events have already occurred), and what will happen to the carbon storage after the project ends. For those projects, we typically seek at least 30 years of project-promised durability and monitoring from the date we buy to take us past the 2050 net-zero target.
- **Over-crediting:** We and our partners look closely at project assumptions to ensure that the project appropriately models its expectations for project emissions and what would have happened if the project did not exist. What's more, we examine what has actually happened for projects when they are already underway—including whether the project assumptions were overly aggressive.

Just as our portfolio will shift in its weight toward removal over time, we will constantly monitor and update the specific projects that make up our portfolio to ensure consistent high quality. As new projects come online and new information about existing projects becomes available, we will continuously evaluate the projects we support so that we can continue to drive climate impact.

Conclusion

Most offset buyers should be purchasing offsets from a diverse array of projects to create a portfolio that aligns with the Oxford Principles. However, building a high-quality, Oxford-aligned portfolio is too hard for all-but the most sophisticated buyers to take on themselves. CNaught democratizes that approach and makes a high-quality portfolio of carbon offsets available to everyone.
